

1 Clone the Starter

Run these three commands in your terminal:

```
npx degit UnkleFrank/astro-wp-starter my-new-site
cd my-new-site
npm install
```

2 Configure Environment

Copy the example file, then edit it with two values:

```
cp .env.example .env
SITE_URL=https://the-new-site.com
WP_URL=https://the-wordpress-site.com
```

3 Test Locally

Starts a local dev server at <http://localhost:4321> — pulls live content from WordPress.

```
npm run dev
```

4 Install the Rebuild Plugin on WordPress

Copy the plugin folder to WordPress, then activate it:

*Copy wp-plugin/astro-rebuild/ → /wp-content/plugins/astro-rebuild/
Then activate in WP Admin → Plugins*

5 Deploy to Cloudflare Pages

Push project to GitHub, then connect in Cloudflare:

*Cloudflare Dashboard → Pages → Create a project → Connect to Git
Build command: `npm run build` Output directory: `dist`
Add env vars: `WP_URL` and `SITE_URL`*

6 Wire Up Auto-Rebuild

One-time setup so WordPress triggers a rebuild automatically on every save:

*Cloudflare Pages → Settings → Builds & deployments → Add deploy hook → copy URL
WP Admin → Settings → Astro Rebuild → paste URL → Save*

That's it. From here, your content editor logs into WordPress, edits a page, hits Publish — Cloudflare rebuilds the site automatically in about 60 seconds. No code, no terminal, nothing else to do.
